

Robotics 1

Robot components: Actuators

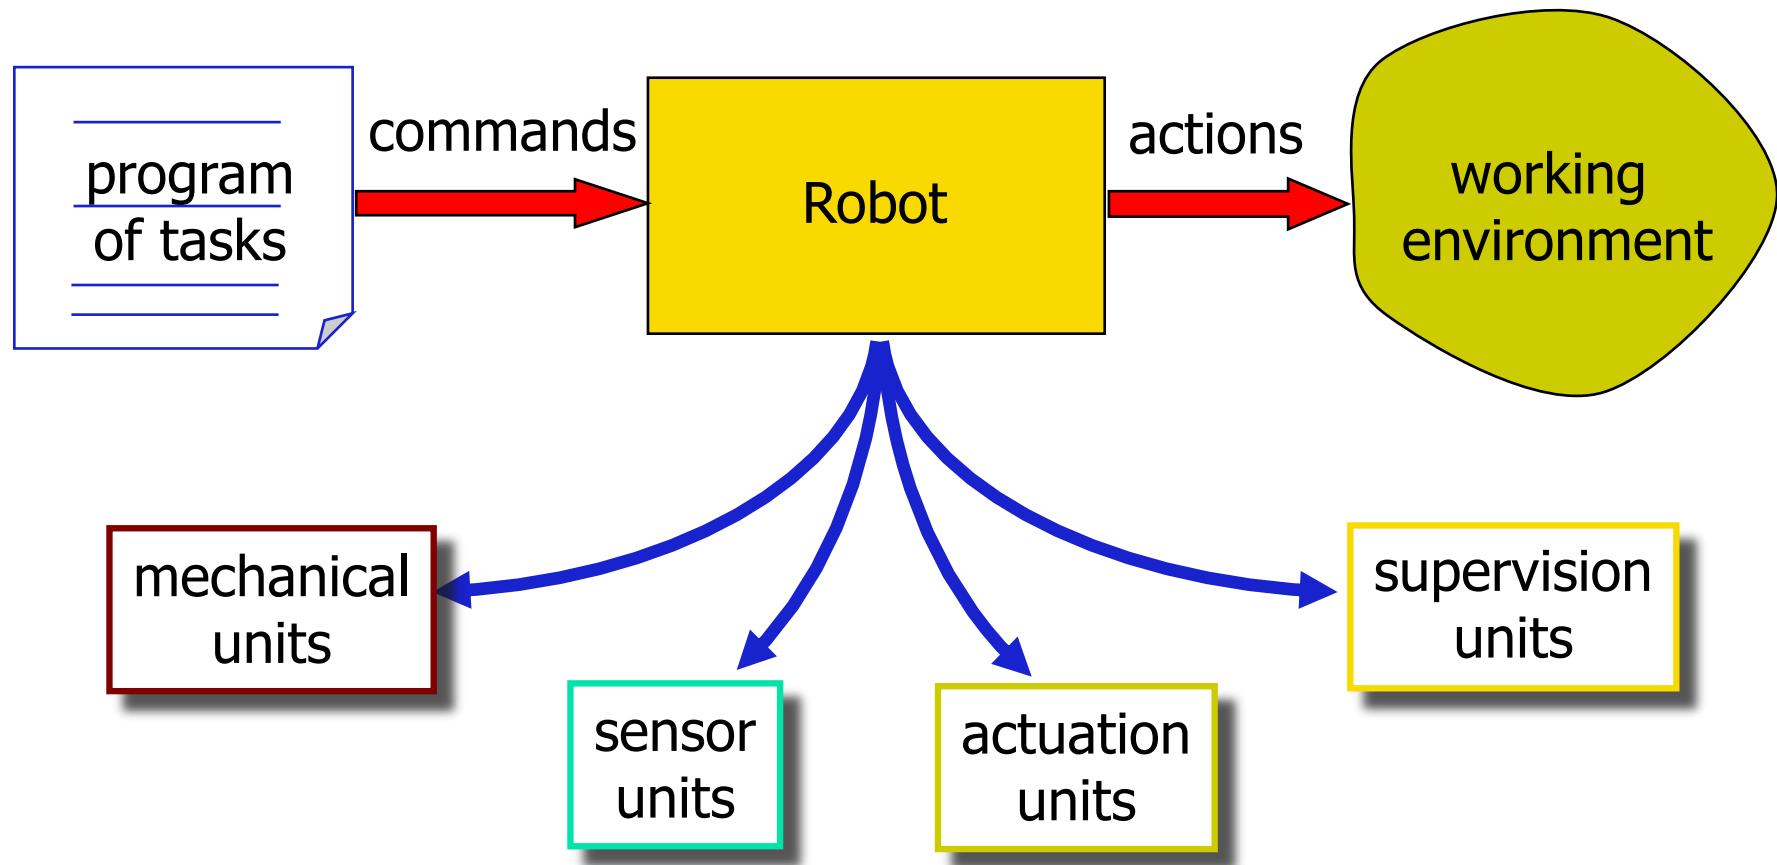

Prof. Alessandro De Luca

DIPARTIMENTO DI INGEGNERIA INFORMATICA
AUTOMATICA E GESTIONALE ANTONIO RUBERTI

Robot as a system

Functional units of a robot

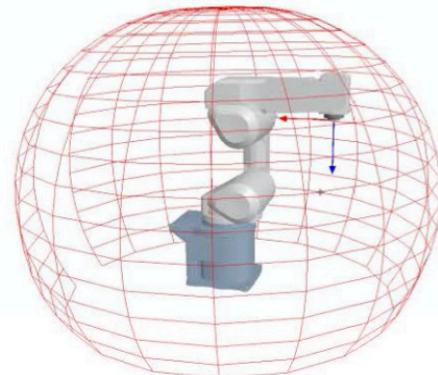

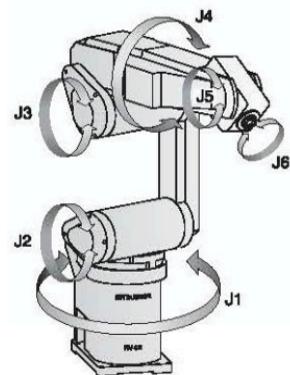

- mechanical units (robot arms)
 - serial manipulators: rigid links connected via **rotational** or **prismatic** joints (each giving 1 degree of freedom = DOF)
 - **supporting structure** (mobility), **wrist** (dexterity), **end-effector** (for task execution, e.g., manipulation)
- actuation units
 - motors (**electrical**, **hydraulic**, **pneumatic**) and transmissions
 - motion control algorithms
- sensor units
 - **proprioceptive** (internal robot state: position and velocity of the joints)
 - **exteroceptive** (external world: force and proximity, vision, ...)
- supervision units
 - task **planning** and **control**
 - artificial intelligence and reasoning

Arrangement of mechanical links

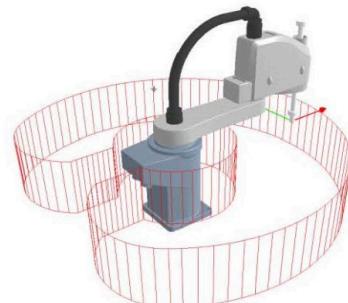

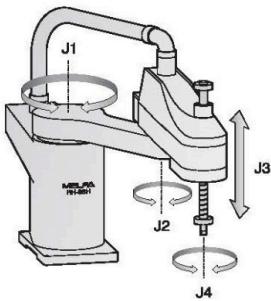

4, 5, or 6 joints (DOFs)

Actuation systems

power = voltage · current = pressure · flow rate = force · speed = torque · angular speed [W, Nm/s]

efficiency = power out/power in [%] energy ~ work = power · time [kWh, Nm, J]

Desired characteristics for robot servomotors

- low inertia
- high power-to-weight ratio
- high acceleration capabilities
 - variable motion regime, with several stops and inversions
- large range of operational velocities
 - 1 to 2000 rpm (round per min)
- high accuracy in positioning
 - at least 1/1000 of a turn
- low torque ripple
 - continuous rotation at low speed
- power: 10 W to 10 kW

Servomotors

- **pneumatic:** pneumatic energy (compressor) → pistons or chambers → mechanical energy
 - difficult to control accurately (change of fluid compressibility) → no trajectory control
 - used for opening/closing grippers
 - ... or as artificial muscles (McKibben actuators)
- **hydraulic:** hydraulic energy (accumulation tank) → pumps/valves → mechanical energy
 - **advantages:** no static overheating, self-lubricated, inherently safe (no sparks), excellent power-to-weight ratio, large torques at low velocity (w/o reduction)
 - **disadvantages:** needs hydraulic supply, large size, linear motion only, low power conversion efficiency, high cost, increased maintenance (oil leaking)

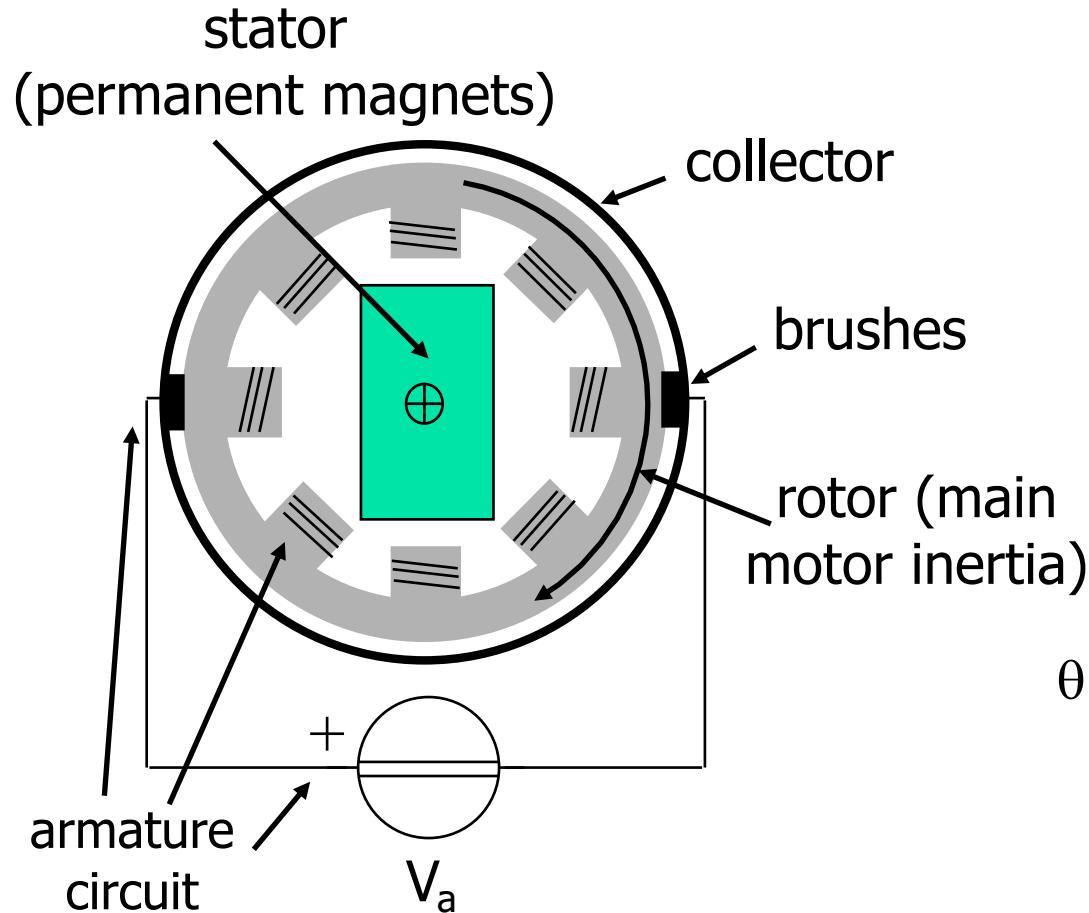

Electrical servomotors

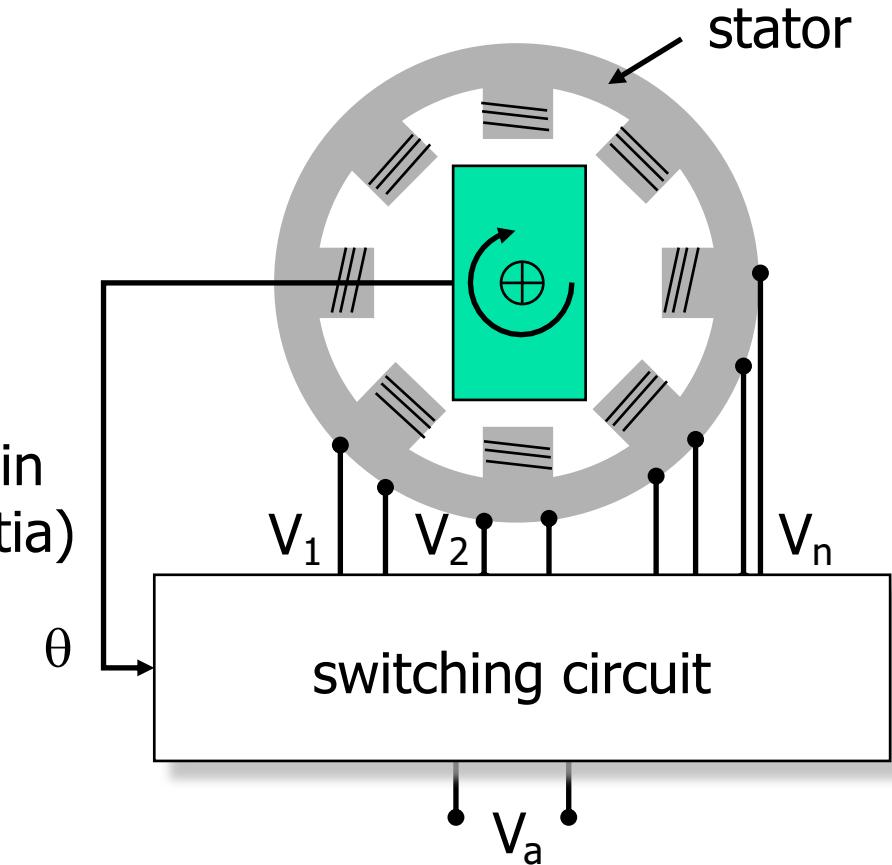

- **advantages**
 - power supply available everywhere
 - low cost
 - large variety of products
 - high power conversion efficiency
 - easy maintenance
 - no pollution in working environment
- **disadvantages**
 - overheating in static conditions (in the presence of gravity)
 - use of emergency brakes
 - need special protection in flammable environments
 - some advanced models require more complex control laws

Electrical servomotors for robots

direct current (DC) motor

with electronic switches (brushless)

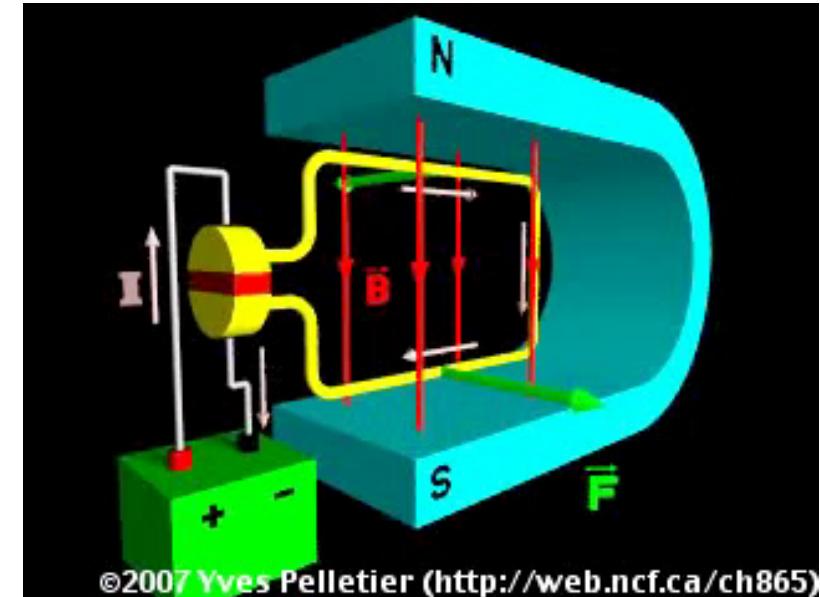

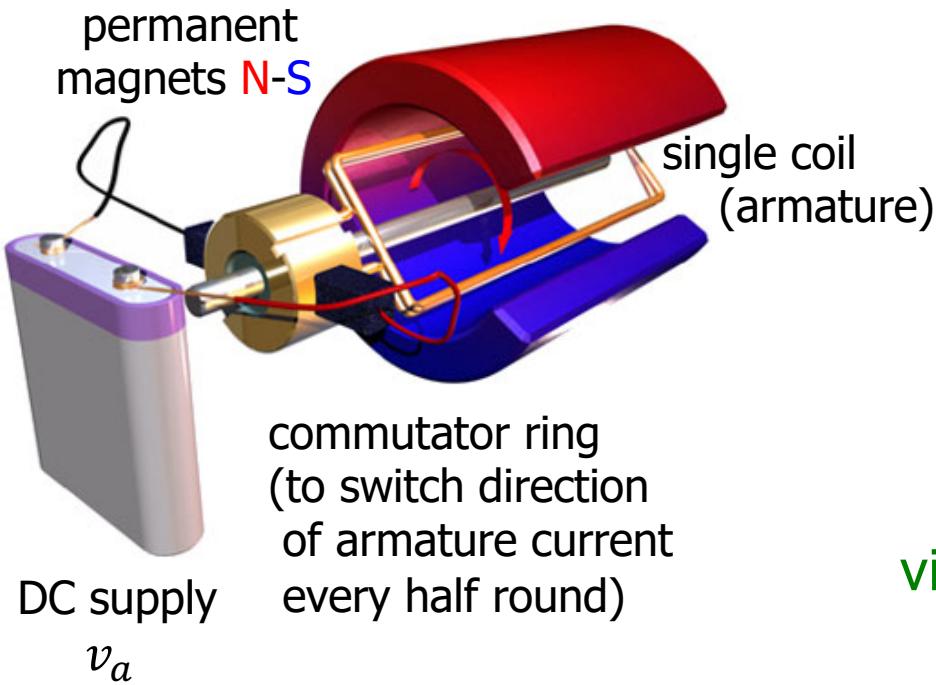

Advantages of brushless motors

- reduced losses, both electrical (due to tension drops at the collector-brushes contacts) and mechanical (friction)
- reduced maintenance (no substitution of brushes)
- easier heat dissipation
- more compact rotor (less inertia and smaller dimensions)

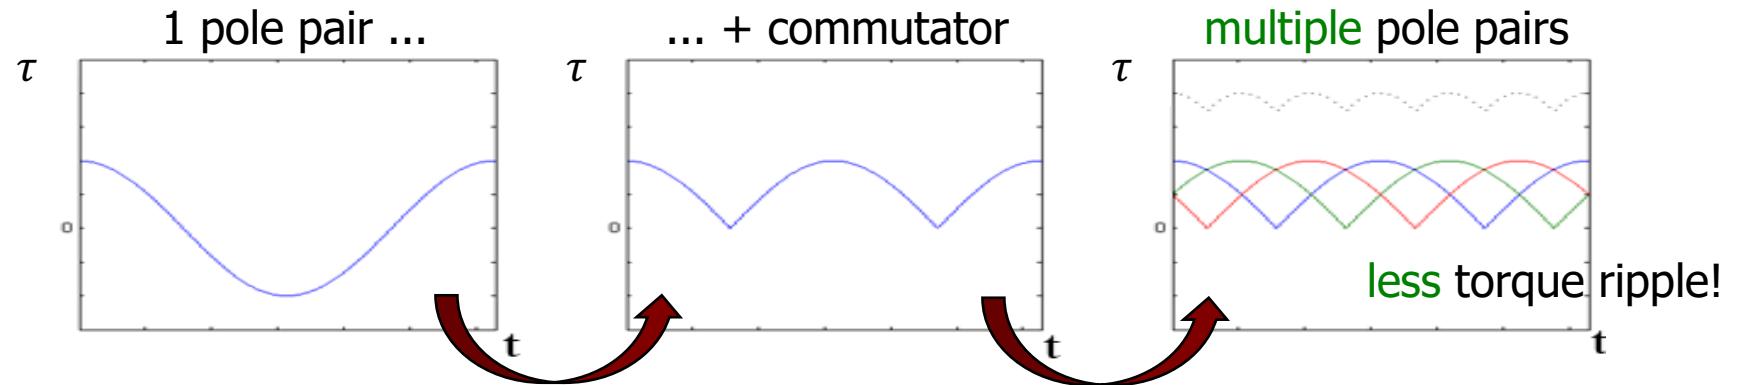

... but indeed a higher cost!

Principle of operation of a DC motor

$$\vec{F} = L(\vec{i} \times \vec{B}) \quad \tau = d|\vec{F}|$$

DC electrical motor

mathematical model (in the time domain)

electrical balance
(on the equivalent armature circuit)

$$v_a(t) = R_a i_a(t) + L_a \frac{di_a(t)}{dt} + v_{emf}(t)$$

$$v_{emf}(t) = k_v \omega(t)$$

(back emf)

mechanical balance
(Newton law on torques)

$$\tau_m(t) = I_m(t) \frac{d\omega(t)}{dt} + F_m \omega(t) + \tau_{load}(t)$$

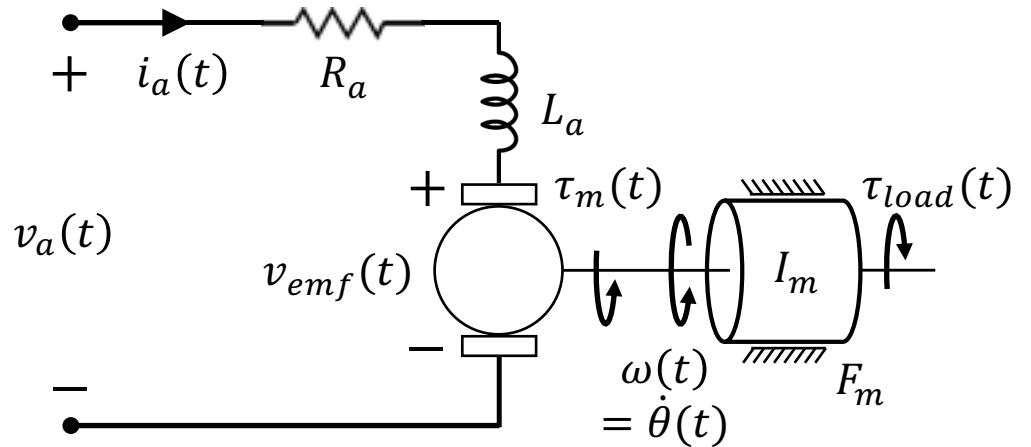

$$\tau_m(t) = k_t i_a(t)$$

(motor torque)

in absence of losses, conservation of power holds in energy transformation

$$P_{elec} = v_{emf} i_a = \tau_m \omega = P_{mecc}$$

$$\Rightarrow k_v = k_t \quad (\text{in SI units})$$

using Laplace transform, differential equations become algebraic relations!

$$X(s) = \mathcal{L}[x(t)] = \int_0^{\infty} x(t) e^{-st} dt$$

DC electrical motor

mathematical model for command and control

electrical balance

$$V_a = (R_a + sL_a) I_a + V_{\text{emf}}$$

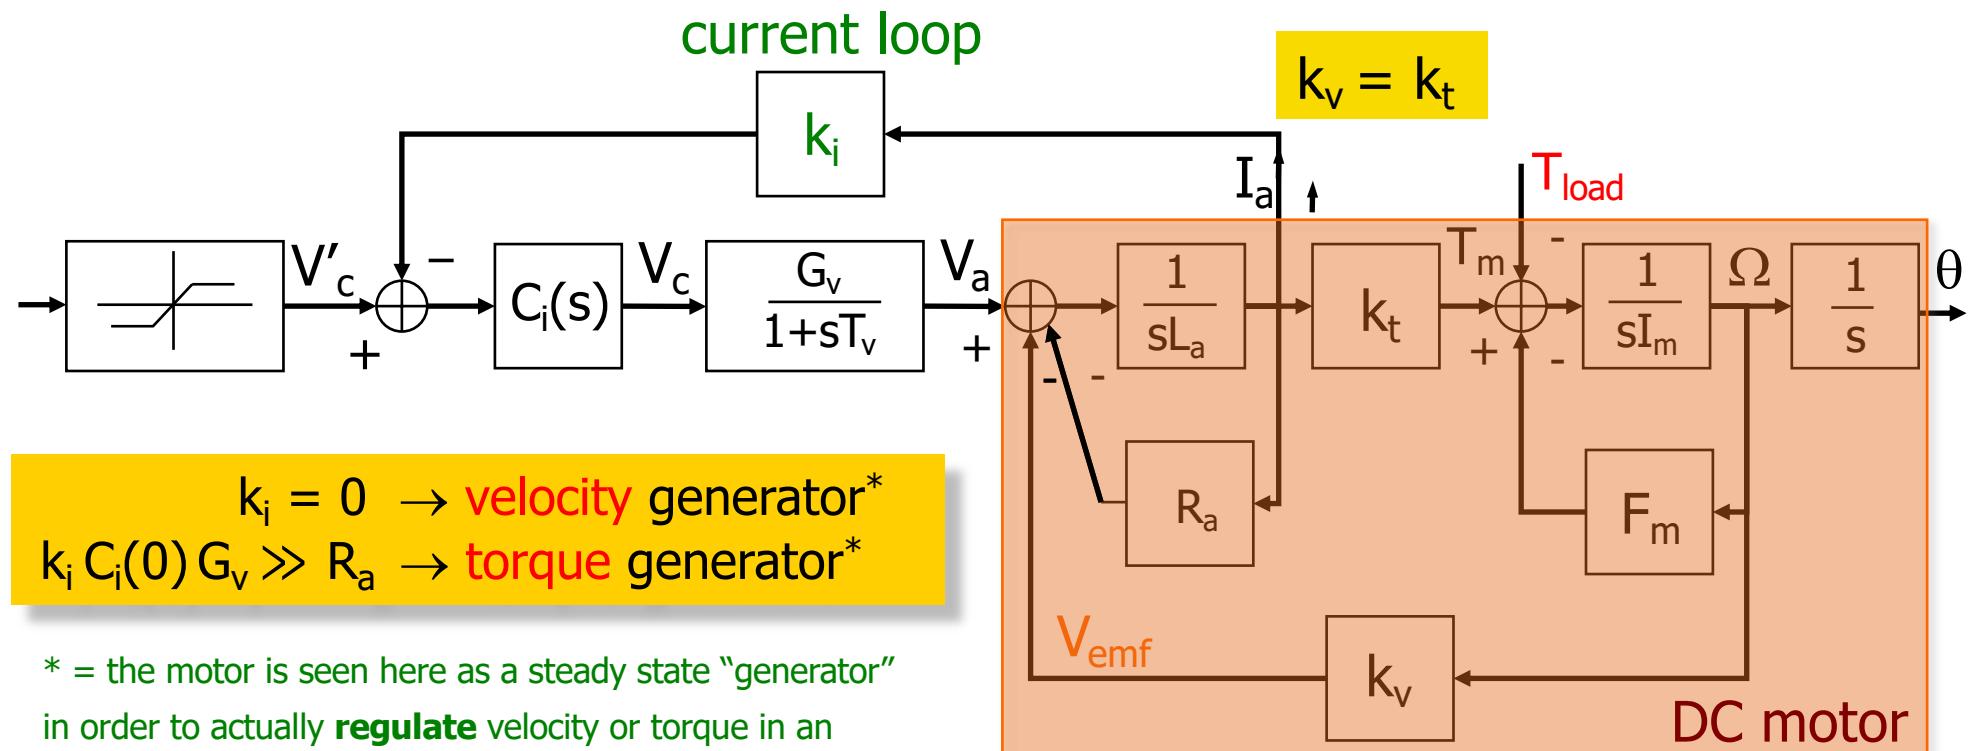

$$V_{\text{emf}} = k_v \Omega$$

Laplace domain (transfer functions)

mechanical balance

$$T_m = (sI_m + F_m) \Omega + T_{\text{load}}$$

$$T_m = k_t I_a$$

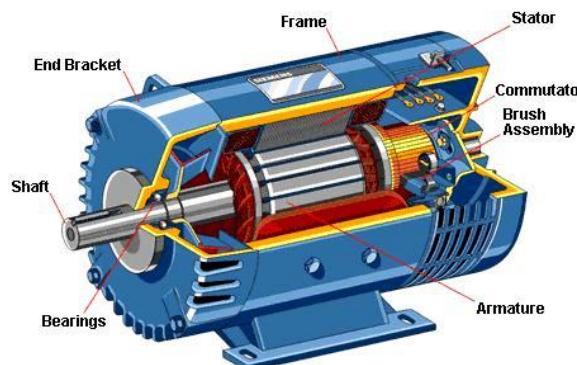

* = the motor is seen here as a steady state "generator"
in order to actually **regulate** velocity or torque in an
efficient way against T_{load} , further control loops are needed!

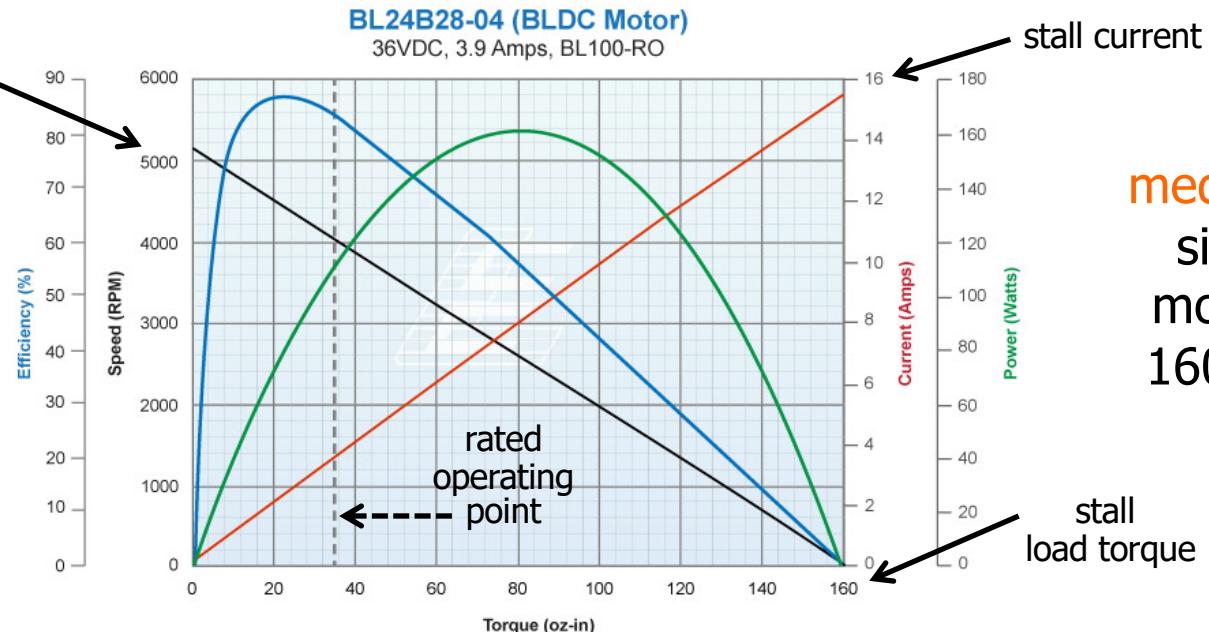

Characteristic curves of a DC motor

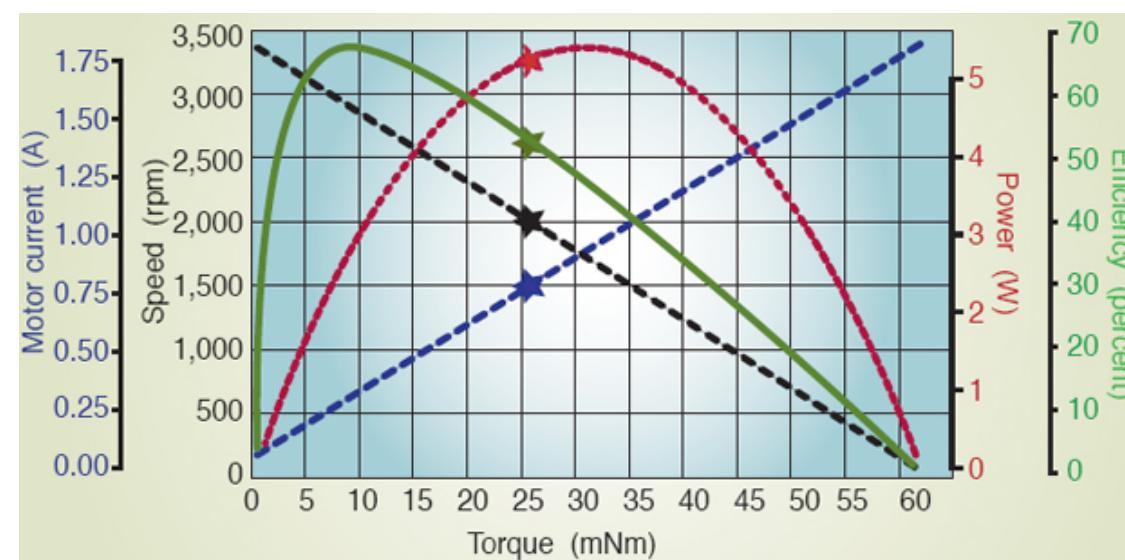

at steady-state,
for **constant**
applied tension v_a

no-load
max speed

conversion SI \leftrightarrow US
unit systems (!!)
 $1 \text{ Nm} = 141.61 \text{ oz-in}$
 $100 \text{ oz-in} = 0.70 \text{ Nm}$

- for applications requiring a rapid and accurate response (in robotics!)
- induction motors driven by alternate current (AC)
- small diameter rotors, with low inertia for fast starts, stops, and reversals

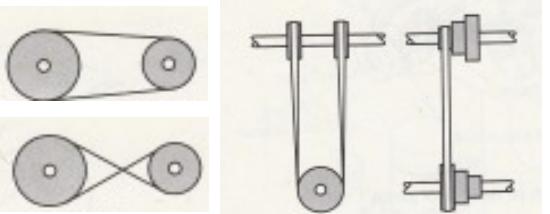

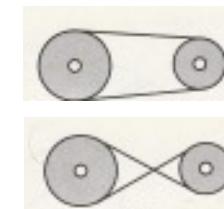

Motion transmission gears

- optimize the transfer of mechanical torque from actuating motors to driven links
- quantitative transformation (from **low torque/high velocity** to **high torque/low velocity**)
- qualitative transformation (e.g., from **rotational** motion of an electrical motor to a **linear** motion of a link along the axis of a prismatic joint)
- allow improvement of static and dynamic performance by reducing the weight of the actual robot structure in motion (locating the motors remotely, closer to the robot base)

Transmissions in robotics

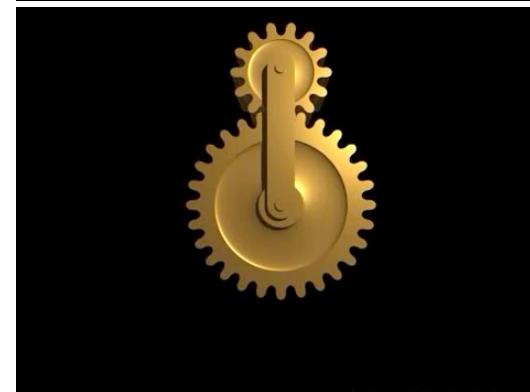

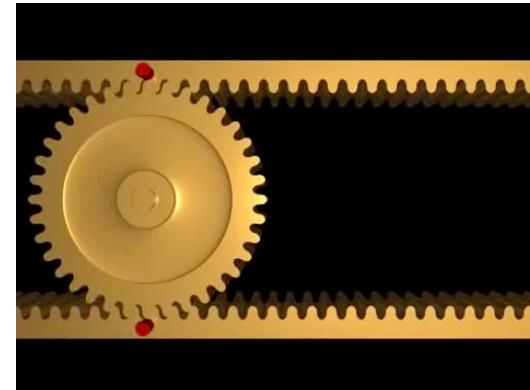

- **spur gears:** modify direction and/or translate axis of (rotational or translational) motor displacement
 - problems: **deformations, backlash**
- **lead screws, worm gearing:** convert rotational into translational motion (prismatic joints)
 - problems: **friction, elasticity, backlash**
- **toothed belts and chains:** dislocate the motor w.r.t. the joint axis
 - problems: **compliance** (belts) or **vibrations** induced by larger mass at high speed (chains)
- **harmonic drives:** compact, in-line, power efficient, with high reduction ratio (up to 150-200:1)
 - problems: **elasticity**
- **transmission shafts:** long, inside the links, with flexible couplings for alignment

Transmission gears in motion

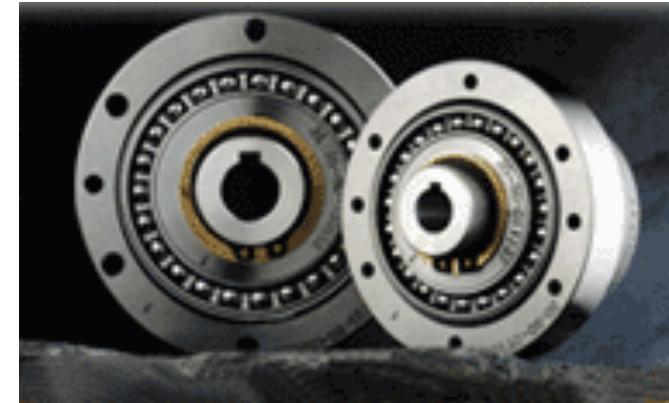

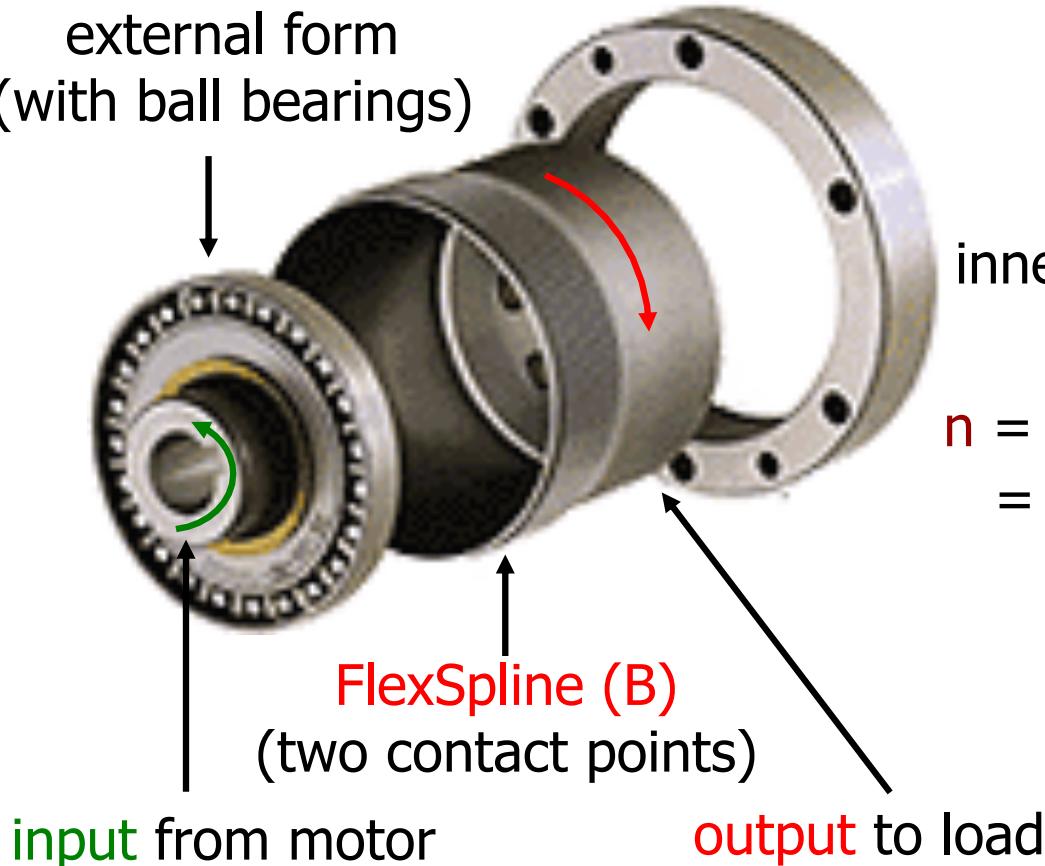

- racks and pinion
 - one rack moving (or both)
- epi-cycloidal gear train
 - or hypo-cycloidal (small gear inside)
- planetary gear set
 - one of three components is locked:
sun gear, planet carrier, ring gear

Harmonic drives

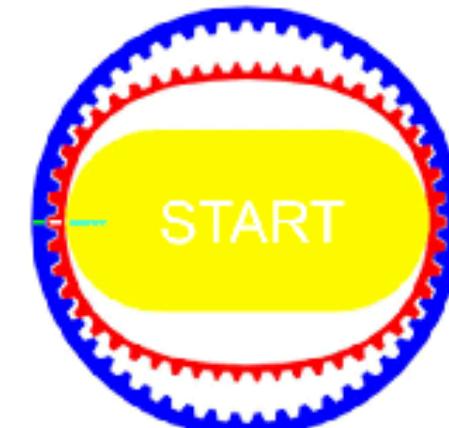

Wave Generator (C)
of slightly elliptic
external form
(with ball bearings)

$$\text{inner \#teeth CS} = \text{outer \#teeth FS} + 2$$

reduction ratio

$$n = \frac{\text{\#teeth FS}}{\text{\#teeth CS} - \text{\#teeth FS}} = \frac{\text{\#teeth FS}}{2}$$

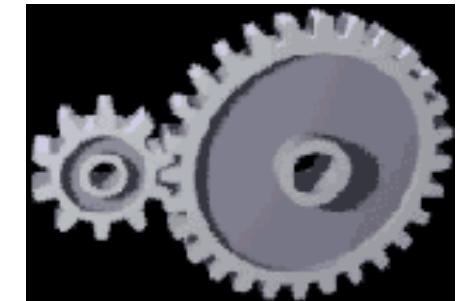

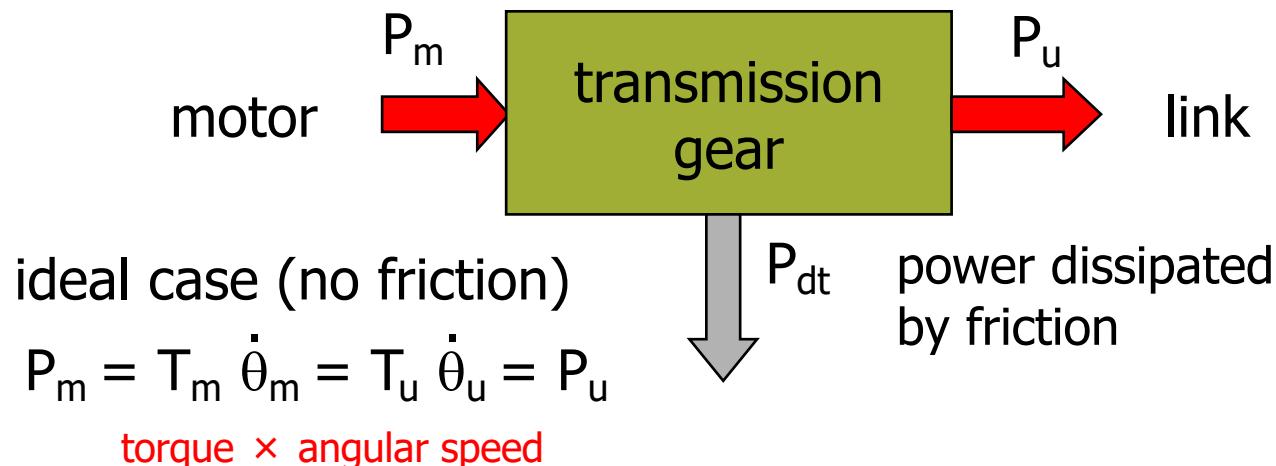

Operation of an harmonic drive

Harmonic Drive Gearing
PRINCIPLE *of* OPERATION

commercial video by Harmonic Drives AG

Optimal choice of reduction ratio

$$n = \text{reduction ratio } (\gg 1) \quad \dot{\theta}_m = n \dot{\theta}_u \quad \rightarrow \quad T_u = n T_m$$

to have $\ddot{\theta}_u = a$ (thus $\ddot{\theta}_m = n a$), the motor should provide a torque

$$T_m = J_m \ddot{\theta}_m + 1/n (J_u \ddot{\theta}_u) = (J_m n + J_u/n) a$$

inertia × angular acceleration

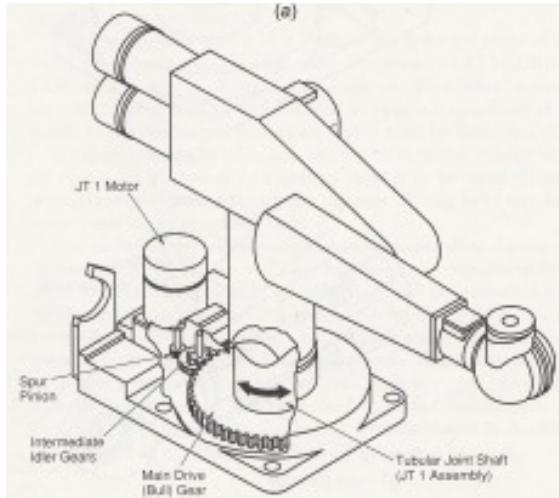

for minimizing T_m , we set: $\frac{\partial T_m}{\partial n} = (J_m - J_u/n^2) a = 0$

→ $n = (J_u / J_m)^{1/2}$ “matching” condition between inertias
